Abstract:
The high energy ball-milling (HEBM) procedure has been used for the preparation of magnetically hard/soft (1−x)SrFe$_{12}$O$_{19}$/xCo nanocomposite (with x = 0.1, 0.2 and 0.3). Effects of aging temperatures (800 - 1000 °C) on microstructure, morphology and magnetic properties have been studied. X-ray diffraction spectrum indicates the existence of two phases: the hexagonal SrFe$_{12}$O$_{19}$ and Co after HEBM process. Scanning electron microscopy was used to characterize the morphology, size and elemental composition of the synthesized nanocomposites. Thermal gravimetric analysis/differential scanning calorimetry were used to estimate the phase transition temperatures of the nanocomposites. The magnetic characterization was carried out via vibrating sample magnetometer at room temperature for the nanocomposite that showed the magnetically single-phase behavior. With increasing the content of Co, the coercivity ($H_c$) of the nanocomposites is decreased. Specific saturation magnetization ($\sigma_s$) is clearly increased with increasing of aging temperatures until reached the maximum ($\sigma_s = 110$ Am$^2$/kg) with $x = 0.1$ aged at 1000 °C. The nanocomposite with $x = 0.1$ aged at 800 °C has enhancement in the squareness ratio ($\sigma_r/\sigma_s$) that reached to 10.2% increment in comparison with the single phase SrFe$_{12}$O$_{19}$. The HEBM process and synthesized SrFe$_{12}$O$_{19}$/Co nanocomposite can be regarded as a suitable technique for preparing hard magnetic nanomaterial for permanent magnets.

Keywords: Ball-milling, nanocomposite, SrFe$_{12}$O$_{19}$, single-phase

1. INTRODUCTION

Hard/soft magnetic nanocomposites (NCs) have aroused great interest due to the tremendous progress in their magnetic properties [1]. By optimizing the composition, the aging temperature and the appropriate ratio of hard/soft magnetic phases, the structure and magnetic performances of these NCs can be enhanced [2,3]. Hard/soft magnetic NCs were produced using the electrospinning method [4], sol-gel procedure [5] and high energy ball milling (HEBM) process [6, 7]. At the HEBM method, there is a noticeable a “kink” or “bee-waist” at the demagnetization loops, suggesting decoupling between hard and soft phases due to the very large soft-phase grains [7]. In this study, hard/soft (1-x)SrFe$_{12}$O$_{19}$/xCo ($x = 0.1, 0.2$, and 0.3) NCs materials have been synthesized using the HEBM method, with an effort to significantly increase the hard /soft exchange-coupling. The effects of the mass ratio of the hard/soft phases and the aging temperature on the morphology, microstructure and magnetic performances of the hard/soft NCs are discussed.

2. EXPERIMENTAL

Hard/soft (1-x)SrFe$_{12}$O$_{19}$/xCo (with $x = 0.1, 0.2$ and 0.3) NCs was synthesized by the HEBM process. Commercially SrFe$_{12}$O$_{19}$ and Co powders of magnetic properties ($H_c = 125, 16.7$ kA/m, $\sigma_s = 57.41, 165$ Am$^2$/kg
and \( \sigma_r/\sigma_s = 0.441 \), respectively, were mixed with 2 ml of acetone in a stainless-steel ball mill vial. The Aktivator 2S planetary ball mill was used for milling at a speed of 800 rpm. The sample was milled for 6 hours at room temperature with mass ratio of a ball to powder 10/1. An analogous synthesis process was used to produce other mass ratio composite precursors. Finally, the \((1-x)\text{SrFe}_{12}\text{O}_{19}/x\text{Co}\) composite precursor was aged at 800, 900, and 1000 °C for 2 h, respectively. A Netzsch STA 409 PC/PG thermogravimetric analyser was used for differential scanning calorimetry (DSC)/thermal gravimetric analysis (TGA) measurement. The structure characterization of NCs was carried out by a DRON-4 diffractometer using Co-K\(\alpha\) radiation. The morphology and elemental analysis of the powders was achieved using a Bruker Quantax 200 energy dispersive X-ray spectroscopy (EDX). Magnetic measurements were done at room temperature using a vibrating sample magnetometer (VSM-250) under an applied magnetic field up to 1600 kA/m.

3. RESULTS AND DISCUSSION

3.1. X-ray powder diffraction

Figures (1a, b, and c) show the diffraction peaks of the composition, confirming the presence of M-type hexaferrite \(\text{SrFe}_{12}\text{O}_{19}\) (SFO) as the hard phase and \(\text{CoFe}_2\text{O}_4\) spinel ferrite (CFO) as the soft phase.

![Figure 1](attachment:image.png)

Figure 1 XRD patterns of \((1-x)\text{SrFe}_{12}\text{O}_{19}/x\text{Co}\) composites with different mass ratio of hard/soft ferrites: (a) 9:1, (b) 8:2, (c) 7:3, (d) after ball milling process
Figure 1d indicates the existence of two phases: the hexagonal SrFe$_{12}$O$_{19}$ and Co after HEBM process. As the concentration and aging temperature increase, the diffraction peaks of CFO gradually increase [5]. There is no metal Co peak in the spectrum, indicating that Co ions are located in the crystal sites of the SFO structure and form a CFO phase [8]. At 800 °C, the presence of the Co$_3$O$_4$ phase is related to an incomplete aging reaction. When the aging temperature is increased, the occurrence of a high proportion of CFO phase.

The decrease in the relative intensity of the peaks may be due to the substituted ions replacing the occupied ions at the lattice sites. The Co ion preferably occupies the 4f2 and 2a positions of the Fe ion octahedron [9].

As shown in Table 1, according to XRD data analysis, the lattice parameters (a and c) and the unit cell volume ($V_{cell}$) are calculated. Compared with the parent structure ($a = 0.5881$ nm and $c = 2.3052$ nm [8], the value of the lattice parameter of the SFO phase is increased from $a = 2.3003$ to $2.3076$ nm; $c = 0.5873$ to $0.5887$ nm with an increase in Co content from 0.1 to 0.3 wt% and increasing aging temperature from 800 to 1000 °C. This increase is attributed to the fact that the ionic radius of the cation Co$^{2+}$ (0.074 nm) is larger than that of Fe$^{3+}$ (0.064 nm) [8]. Due to the increase in $a$ and $c$, the $V_{cell}$ also increased from 0.687 to 0.6926 nm$^3$.

Table 1 shows the increase of average crystallite size $<D>$, as the aging temperature of all samples was increased from 800 to 1000 °C, demonstrates that grain growth arises during the aging process.

#### 3.2. Differential scanning calorimetry

The DSC/TGA analysis of 0.9SrFe$_{12}$O$_{19}$/0.1Co NCs heated at a rate of 10 °C/min was performed. As illustrated in Figure 2, the DSC curve shows a strong endothermic peak near 902 °C. This is due to the transition from Co$_3$O$_4$ to CoO and the formation of CFO spinel. The small endothermic peak from 900 to 1100 °C may be due to decomposition of a small amount of SrFe$_{12}$O$_{19}$ and the formation of SrFeO$_3$. From the TGA curve, the 2.2% weight loss is mainly caused by the decomposition of Co$_3$O$_4$ into CoO and SrFe$_{12}$O$_{19}$ into SrFeO$_3$ [10].
3.3. The morphology

Figure 3 shows SEM image and the results of a representative EDX mapping analysis of 0.9SrFe$_{12}$O$_{19}$/0.1Co NCs. It can be clearly observed that all relevant elements (Sr, Fe, O and Co) are evenly distributed; confirm that these two phases are evenly distributed in the NC.

3.4. Magnetic hysteresis properties

Figure 4 shows the hysteresis loop of (1-x)SrFe$_{12}$O$_{19}$/xCo (x = 0.1, 0.2, 0.3) NCs at room temperature. The powder sample (x = 1) shows hysteresis, indicating that it has hard magnetic properties. However, as the Co content (x) increases, the hysteresis loop becomes smaller, and the magnetization curve shows moderate hard magnetic characteristics at x = 0.3, which indicates that the magnetic anisotropy is reduced by the
substitution of Sr(Fe,Co)\textsubscript{12}O\textsubscript{19}. From the smooth demagnetization curve of NCs, an exchange coupled between the magnetically hard/soft phases can be observed [5].

As shown in the Figure 5a, the $H_c$ of (1-x)SrFe\textsubscript{12}O\textsubscript{19}/xCo (x = 0.1, 0.2 and 0.3) decreases monotonously with the increase of x and aging temperature. The 0.1Co/0.9SrFe\textsubscript{12}O\textsubscript{19} NCs, aged at 800 °C, have the maximum $H_c$ (214.9 kA/m); while the 0.3Co/0.7SrFe\textsubscript{12}O\textsubscript{19} NCs, aged at 1000 °C, have the minimum $H_c$ (39.8 kA/m).

This can be attributed to the large crystal grains, it is easy to cause domain wall movement, thus reducing $H_c$ [11]. In addition, as the aging temperature increases, the volume fraction of CFO increases and $H_c$ decreases owing to the fact that the $H_c$ of SFO/CFO NCs is not as large as that of SFO ferrite.

The $\sigma_s$ of (1-x) SrFe\textsubscript{12}O\textsubscript{19}/xCo (x = 0.1, 0.2 and 0.3) increases as the calcination temperature increases. In addition, as shown in Figure 5b, the $\sigma_s$ of NCs varies nonlinearly with x. Herein, the 0.9SrFe\textsubscript{12}O\textsubscript{19}/0.1Co NCs powder, aged at 1000 °C, has the highest $\sigma_s$ value (110 Am\textsuperscript{2}/kg). This can be ascribed to the exchange coupled between the magnetically hard/soft phases. Furthermore, the magnetic moment of Co\textsuperscript{2+} (3 μB) is not as large as that of Fe\textsuperscript{3+} (5 μB), so replacing Fe\textsuperscript{3+} with Co\textsuperscript{2+} instead of 4f2 will increase the $\sigma_s$ of the composite material [12]. The 0.7SrFe\textsubscript{12}O\textsubscript{19}/0.3Co NCs, aged at 800 °C, has the lowest $\sigma_s$ value (65 Am\textsuperscript{2}/kg). As the Co substitution increases, the tetrahedral-octahedral exchange interaction between Fe\textsuperscript{3+} and O\textsuperscript{2-} ions weakens, so the magnetic moment value of the system decreases [13].

Remanence ($\sigma_r$) of (1-x)SrFe\textsubscript{12}O\textsubscript{19}/xCo increases with the increase in aging temperature. As shown in Figure 5c, the $\sigma_r$ trend of (1-x) SrFe\textsubscript{12}O\textsubscript{19}/xCo decreases as x increases. Due to the exchange coupled between the magnetically hard/soft phases, $\sigma_r$ will be generated in the prepared nanocomposite powder.

Figure 4 Magnetic hysteresis loops of (1-x) SrFe\textsubscript{12}O\textsubscript{19}/xCo composites with different mass ratio of hard/soft ferrites: (a) 9:1, (b) 8:2 and (c) 7:3
The dependence $\sigma_r/\sigma_s$ on aging temperature and $x$ is shown in Figure 5d. The $\sigma_r/\sigma_s$ of $(1-x)$ SrFe$_{12}$O$_{19}$/xCo decreased with the increase of aging temperature and showed a nonlinear change with the increase $x$. The theoretically predictable value of up to 0.50 is attributed to the single domain structure. As the volume fraction of the CFO increases in the NCs, the $\sigma_r/\sigma_s$ decreased from 0.489 at 800 °C to 0.352 at 1000 °C. All values of $\sigma_r/\sigma_s$ are lower than 0.5, which indicates that all NCs have multi-domain characteristics [2].

Figure 5 Variation in (a) Coercivity ($H_c$), (b) specific saturation magnetization ($\sigma_s$), (c) remanence ($\sigma_r$) and (d) squareness ratio ($\sigma_r/\sigma_s$) as function of Co content ($x$) and aging temperature of the $(1-x)$ SrFe$_{12}$O$_{19}$/xCo NCs

CONCLUSION

Hard/soft (1−$x$)SrFe$_{12}$O$_{19}$/xCo NCs (with $x = 0.1$, 0.2 and 0.3) was successfully prepared using the HEBM process. The maximum magnetic properties ($H_c = 214.9$ kA/m, $\sigma_s = 82.68$ Am$^2$/kg and $\sigma_r/\sigma_s = 0.489$) were achieved for 0.9SrFe$_{12}$O$_{19}$/0.1Co NCs, aged at 800 °C. Excessive Co and higher aging temperature will cause defects in the main hard magnetic SrFe$_{12}$O$_{19}$ phase and increase the amount of CoFe$_2$O$_4$ soft magnetic phase, thereby reducing the magnetic properties.

Future work will focus on the synthesis of different composites with lower cost and higher performance.
